1 INTRODUCTION

1.1 Job Design

Job design is an aspect of managing organizations that is so commonplace it often goes unnoticed. Most people realize the importance of job design when an organization or new plant is starting up, and some recognize the importance of job design when organizations are restructuring or changing processes. But fewer people realize that job design may be affected as organizations change markets or strategies, managers use their discretion in the assignment of tasks on a daily basis, people in the jobs or their managers change, the workforce or labor markets change, or there are performance, safety, or satisfaction problems. Fewer yet realize that job design change can be used as an intervention to enhance organizational goals (Campion and Medsker, 1992).

It is clear that many different aspects of an organization influence job design, especially an organization’s structure, technology, processes, and environment. These influences are beyond the scope of this chapter, but they are dealt with in other references (e.g., Davis, 1982; Davis and Wacker, 1982). These influences impose constraints on how jobs are designed and will play a major role in any practical application. However, it is the assumption of this chapter that considerable discretion exists in the design of jobs in most situations, and the job (defined as a set of tasks performed by a worker)
is a convenient unit of analysis in both developing new organizations or changing existing ones (Campion and Medsker, 1992).

The importance of job design lies in its strong influence on a broad range of important efficiency and human resource outcomes. Job design has predictable consequences for outcomes including the following (Campion and Medsker, 1992):

1. Productivity
2. Quality
3. Job satisfaction
4. Training times
5. Intrinsic work motivation
6. Staffing
7. Error rates
8. Accident rates
9. Mental fatigue
10. Physical fatigue
11. Stress
12. Mental ability requirements
13. Physical ability requirements
14. Job involvement
15. Absenteeism
16. Medical incidents
17. Turnover
18. Compensation rates

According to Louis Davis, one of the most prolific writers on job design in the engineering literature over the last 35 years, many of the personnel and productivity problems in industry may be the direct result of the design of jobs (Davis, 1957; Davis et al., 1955; Davis and Taylor, 1979; Davis and Valfer, 1965; Davis and Wacker, 1982, 1987). Unfortunately, people mistakenly view the design of jobs as technologically determined and inalterable. However, job designs are actually social inventions. They reflect the values of the era in which they were constructed. These values include the economic goal of minimizing immediate costs (Davis et al., 1955; Taylor, 1979) and theories of human motivation (Steers and Mowday, 1977; Warr and Wall, 1975). These values, and the designs they influence, are not immutable givens but are subject to modification (Campion and Medsker, 1992; Campion and Thayer, 1985).

The question then becomes: What is the best way to design a job? In fact, there is no single best way. There are several major approaches to job design, each derived from a different discipline and reflecting different theoretical orientations and values. This chapter describes these approaches, their costs and benefits, and tools and procedures for developing and assessing jobs in all types of organizations. It highlights trade-offs which must be made when choosing among different approaches to job design. This chapter also compares the design of jobs for individuals working independently to the design of work for teams, which is an alternative to designing jobs at the level of individual workers. This chapter presents the advantages and disadvantages of designing work around individuals compared to designing work for teams and provides advice on implementing and evaluating the different work design approaches.

1.2 Team Design

The major approaches to job design typically focus on designing jobs for individual workers. However, the approach to work design at the level of the group or team, rather than at the level of individual workers, is gaining substantially in popularity, and many U.S. organizations are experimenting with teams (Guzzo and Shea, 1992; Hoerr, 1989). New manufacturing systems (e.g., flexible, cellular) and advancements in our understanding of team processes not only allow designers to consider the use of work teams but often seem to encourage the use of team approaches (Gallagher and Knight, 1986; Majchrzak, 1988).

In designing jobs for teams, one assigns a task or set of tasks to a team of workers, rather than to an individual, and considers the team to be the primary unit of performance. Objectives and rewards focus on team, not individual, behavior. Depending on the nature of its tasks, a team’s workers may be performing the same tasks simultaneously or they may break tasks into subtasks to be performed by individuals within the team. Subtasks can be assigned on the basis of expertise or interest, or team members might rotate from one subtask to another to provide variety and increase breadth of skills and flexibility in the workforce (Campion and Medsker, 1992; Campion et al., 1994b).

Some tasks are of a size or complexity or otherwise seem to naturally fit into a team job design, whereas others may seem to be appropriate only at the individual job level. In many cases, though, there may be a considerable degree of choice regarding whether one organizes work around teams or individuals. In such situations, the designer should consider advantages and disadvantages of the use of the job and team design approaches with respect to an organization’s goals, policies, technologies, and constraints (Campion et al., 1993).

2 JOB DESIGN APPROACHES

This chapter adopts an interdisciplinary perspective on job design. Interdisciplinary research on job design has shown that different approaches to job design exist. Each is oriented toward a particular subset of outcomes, each has disadvantages as well as advantages, and trade-offs among approaches are required in most job design situations (Campion, 1988, 1989; Campion and Berger, 1990; Campion and McClelland, 1991, 1993; Campion and Thayer, 1985; Edwards et al., 1999, 2000; Morgeson and Campion, 2002, 2003).

While not new, contemporary work design researchers and practitioners have begun to reintegrate social and contextual aspects of employees’ work with the characteristics traditionally studied by job design. These approaches to work design have since led to new approaches and have become incorporated into new assessment tools (Morgeson and Humphrey, 2006; Morgeson et al., 2010; Humphrey et al., 2007; Grant and
The historical roots of job design can be traced back to the idea of the division of labor, which was very important to early thinking on the economies of manufacturing (Babbage, 1835; Smith, 1776). Division of labor led to job designs characterized by specialization and simplification. The four major approaches to job design are reviewed below with a discussion of the applicability of each approach.

2.1 Mechanistic Job Design Approach

2.1.1 Historical Development

The historical roots of job design can be traced back to the idea of the division of labor, which was very important to early thinking on the economies of manufacturing (Babbage, 1835; Smith, 1776). Division of labor led to job designs characterized by specialization and simplification. Jobs designed in this fashion had many advantages, including reduced learning time, saved time from not having to change tasks or tools, increased proficiency from repeating tasks, and development of specialized tools and equipment.

A very influential person for this perspective was Frederick Taylor (Hammond, 1971; Taylor, 1911). He explicated the principles of scientific management, which encouraged the study of jobs to determine the “one best way” to perform each task. Movements of skilled workmen were studied using a stopwatch and simple analysis. The best and quickest methods and tools were selected, and all workers were trained to perform the job the same way. Standard performance levels were set, and incentive pay was tied to the standards. Gilbreth (1911) also contributed to this design approach. With time-and-motion study, he tried to eliminate wasted movements by the appropriate design of equipment and placement of tools and materials.

Surveys of industrial job designers indicate that this “mechanistic” approach to job design has been the prevailing practice throughout this century (Davis et al., 1955; Taylor, 1979). These characteristics are also the primary focus of many modern-day writers on job design (e.g., Mundel, 1985; Niebel, 1988) and are present in such newer techniques as lean production (Parker, 2003). The discipline base for this approach is early or “classic” industrial engineering.

2.1.2 Design Recommendations

Table 2 provides a brief list of statements that describe the essential recommendations of the mechanistic approach. In essence, jobs should be studied to determine the most efficient work methods and techniques. The total work in an area (e.g., department) should be broken down into highly specialized jobs assigned to different employees. The tasks should be simplified so skill requirements are minimized. There should also be repetition in order to gain improvement from practice. Idle time should be minimized. Finally, activities should be automated or assisted by automation to the extent possible and economically feasible.

2.1.3 Advantages and Disadvantages

The goal of this approach is to maximize efficiency, in terms of both productivity and utilization of human resources. Table 1 summarizes some human resource advantages and disadvantages that have been observed in research. Jobs designed according to the mechanistic approach are easier and less expensive to staff. Training times are reduced. Compensation requirements may be less because skill and responsibility are reduced. And because mental demands are less, errors may be less common. Disadvantages include the fact that extreme use of the mechanistic approach may result in jobs so simple and routine that employees experience low job satisfaction and motivation. Overly mechanistic, repetitive work can lead to health problems such as repetitive-motion disorders.

2.2 Motivational Job Design Approach

2.2.1 Historical Development

Encouraged by the human relations movement of the 1930s (Hoppock, 1935; Mayo, 1933), people began to point out the negative effects of the overuse of mechanistic design on worker attitudes and health (Argyris, 1964; Blauner, 1964). Overly specialized, simplified jobs were found to lead to dissatisfaction (Caplan et al., 1975) and adverse physiological consequences for workers (Johansson et al., 1978; Weber et al., 1980). Jobs on assembly lines and other machine-paced work were especially troublesome in this regard (Salvendy and Smith, 1981; Walker and Guest, 1952). These trends led to an increasing awareness of employees’ psychological needs.

The first efforts to enhance the meaningfulness of jobs involved the opposite of specialization. It was recommended that tasks be added to jobs, either at the

**Source:** Adapted from Campion and Medsker (1992).

**Note:** Advantages and disadvantages based on findings in previous interdisciplinary research (Campion, 1988, 1989; Campion and Berger, 1990; Campion and McClelland, 1991, 1993; Campion and Thayer, 1985). Table adapted from Campion and Medsker (1992).

same level of responsibility (i.e., job enlargement) or at a higher level (i.e., job enrichment) (Ford, 1969; Herzberg, 1966). This trend expanded into a pursuit of identifying and validating characteristics of jobs that make them motivating and satisfying (Griffin, 1982; Hackman and Oldham, 1980; Turner and Lawrence, 1965). This approach considers the psychological theories of work motivation (e.g., Steers and Mowday, 1977; Vroom, 1964); thus this “motivational” approach draws primarily from organizational psychology as a discipline base.

A related trend following later in time but somewhat comparable in content is the sociotechnical approach (Emory and Trist, 1960; Pasmoro, 1988; Rousseau, 1977). It focuses not only on the work but also on the technology itself and the relationship of the environment to work and organizational design. Interest is less on the job and more on roles and systems. Keys to this approach are work system and job designs that fit their external environment and the joint optimization of both social and technical systems in the organization’s internal environment. Though this approach differs somewhat in that consideration is also given to the technical system and external environment, it is similar in that it draws on the same psychological job characteristics that affect satisfaction and motivation. It suggests that as organizations’ environments are becoming...

#### Mechanistic Approach

1. Job specialization: The job is highly specialized in terms of purpose, tasks, or activities. 1 2 3 4 5
2. Specialization of tools and procedures: The tools, procedures, materials, etc., used on this job are highly specialized in terms of purpose. 1 2 3 4 5
3. Task simplification: The tasks are simple and uncomplicated. 1 2 3 4 5
4. Single activities: The job requires you to do only one task or activity at a time. 1 2 3 4 5
5. Skill simplification: The job requires relatively little skill and training time. 1 2 3 4 5
6. Repetition: The job requires performing the same activity(s) repeatedly. 1 2 3 4 5
7. Spare time: There is very little spare time between activities on this job. 1 2 3 4 5
8. Automation: Many of the activities of this job are automated or assisted by automation. 1 2 3 4 5

#### Motivational Approach

9. Autonomy: The job allows freedom, independence, or discretion in work scheduling, sequence, methods, procedures, quality control, or other decision making. 1 2 3 4 5
10. Intrinsic job feedback: The work activities themselves provide direct and clear information as to the effectiveness (e.g., quality and quantity) of job performance. 1 2 3 4 5
11. Extrinsic job feedback: Other people in the organization, such as managers and co-workers, provide information as to the effectiveness (e.g., quality and quantity) of job performance. 1 2 3 4 5
12. Social interaction: The job provides for positive social interaction such as team work or co-worker assistance. 1 2 3 4 5
13. Task/goal clarity: The job duties, requirements, and goals are clear and specific. 1 2 3 4 5
14. Task variety: The job has a variety of duties, tasks, and activities. 1 2 3 4 5
15. Task identity: The job requires completion of a whole and identifiable piece of work. It gives you a chance to do an entire piece of work from beginning to end. 1 2 3 4 5
16. Ability/skill-level requirements: The job requires a high level of knowledge, skills, and abilities. 1 2 3 4 5
17. Ability/skill variety: The job requires a variety of knowledge, skills, and abilities. 1 2 3 4 5
18. Task significance: The job is significant and important compared with other jobs in the organization. 1 2 3 4 5
19. Growth/learning: The job allows opportunities for learning and growth in competence and proficiency. 1 2 3 4 5
20. Promotion: There are opportunities for advancement to higher level jobs. 1 2 3 4 5
21. Achievement: The job provides for feelings of achievement and task accomplishment. 1 2 3 4 5
22. Participation: The job allows participation in work-related decision making. 1 2 3 4 5
23. Communication: The job has access to relevant communication channels and information flows. 1 2 3 4 5
24. Pay adequacy: The pay on this job is adequate compared with the job requirements and with the pay in similar jobs. 1 2 3 4 5
25. Recognition: The job provides acknowledgment and recognition from others. 1 2 3 4 5
26. Job security: People on this job have high job security. 1 2 3 4 5

#### Perceptual/Motor Approach

27. Lighting: The lighting in the workplace is adequate and free from glare. 1 2 3 4 5
28. Displays: The displays, gauges, meters, and computerized equipment on this job are easy to read and understand. 1 2 3 4 5
29. Programs: The programs in the computerized equipment on this job are easy to learn and use. 1 2 3 4 5
30. Other equipment: The other equipment (all types) used on this job is easy to learn and use. 1 2 3 4 5

(Continued overleaf)
increasingly turbulent and complex, organizational and job design should involve greater flexibility, employee involvement, employee training, and decentralization of decision making and control, and a reduction in hierarchical structures and the formalization of procedures and relationships (Pasmore, 1988).

Surveys of industrial job designers have consistently indicated that the mechanistic approach represents the dominant theme of job design (Davis et al., 1955; Taylor, 1979). Other approaches to job design, such as the motivational approach, have not been given as much explicit consideration. This is not surprising because the surveys only included job designers trained in engineering-related disciplines, such as industrial engineering and systems analysis. It is not necessarily certain that other specialists or line managers would adopt the same philosophies, especially in recent times. Nevertheless, there is evidence that even fairly naive job designers (i.e., college students in management classes) also adopt the mechanistic approach in job design simulations. That is, their strategies for grouping tasks were primarily based on such factors as activities, skills, equipment, procedures, or location. Even though the mechanistic approach may be the most natural and intuitive, this research has also revealed that people can be trained to apply all four approaches to job design (Campion and Stevens, 1991). The motivational characteristics of the WDQ are an extension of this motivational approach to job design. This set of characteristics is based on the idea that high levels of these characteristics make work more motivating, satisfying, and enriching. Subcategories of these characteristics include task characteristics (task variety, task significance, task identity, and feedback from the job) and knowledge characteristics (job complexity, information processing, problem solving, skill variety, and specialization).

Building off of the ideas presented in Morgeson and Humphrey’s WDQ, scholars are beginning to examine the social aspects of work design and how they interact.

**Task Characteristics**

**Autonomy/Work Scheduling Autonomy**
1. The job allows me to make my own decisions about how to schedule my work.  
2. The job allows me to decide on the order in which things are done on the job.  
3. The job allows me to plan how I do my work.

**Autonomy/Decision-Making Autonomy**
4. The job gives me a chance to use my personal initiative or judgment in carrying out the work.  
5. The job allows me to make a lot of decisions on my own.  
6. The job provides me with significant autonomy in making decisions.

**Autonomy/Work Methods Autonomy**
7. The job allows me to make decisions about what methods I use to complete my work.  
8. The job gives me considerable opportunity for independence and freedom in how I do the work.  
9. The job allows me to decide on my own how to go about doing my work.

**Task Variety**
10. The job involves a great deal of task variety.  
11. The job involves doing a number of different things.  
12. The job requires the performance of a wide range of tasks.  
13. The job involves performing a variety of tasks.

**Task Significance**
14. The results of my work are likely to significantly affect the lives of other people.  
15. The job itself is very significant and important in the broader scheme of things.  
16. The job has a large impact on people outside the organization.  
17. The work performed on the job has a significant impact on people outside the organization.

**Task Identity**
18. The job involves completing a piece of work that has an obvious beginning and end.  
19. The job is arranged so that I can do an entire piece of work from beginning to end.  
20. The job provides me the chance to completely finish the pieces of work I begin.  
21. The job allows me to complete work I start.

**Feedback from Job**
22. The work activities themselves provide direct and clear information about the effectiveness (e.g., quality and quantity) of my job performance.  
23. The job itself provides feedback on my performance.  
24. The job itself provides me with information about my performance.

**Knowledge Characteristics**

**Job Complexity**
25. The job requires that I only do one task or activity at a time (reverse scored).  
26. The tasks on the job are simple and uncomplicated (reverse scored).  
27. The job comprises relatively uncomplicated tasks (reverse scored).  
28. The job involves performing relatively simple tasks (reverse scored).
Table 3 (continued)

| Information Processing | | | | |
|------------------------|-----------------|
| 29. The job requires me to monitor a great deal of information. | 1 2 3 4 5 |
| 30. The job requires that I engage in a large amount of thinking. | 1 2 3 4 5 |
| 31. The job requires me to keep track of more than one thing at a time. | 1 2 3 4 5 |
| 32. The job requires me to analyze a lot of information. | 1 2 3 4 5 |

| Problem Solving | | | | |
|------------------|-----------------|
| 33. The job involves solving problems that have no obvious correct answer. | 1 2 3 4 5 |
| 34. The job requires me to be creative. | 1 2 3 4 5 |
| 35. The job often involves dealing with problems that I have not met before. | 1 2 3 4 5 |
| 36. The job requires unique ideas or solutions to problems. | 1 2 3 4 5 |

| Skill Variety | | | | |
|----------------|-----------------|
| 37. The job requires a variety of skills. | 1 2 3 4 5 |
| 38. The job requires me to utilize a variety of different skills in order to complete the work. | 1 2 3 4 5 |
| 39. The job requires me to use a number of complex or high-level skills. | 1 2 3 4 5 |
| 40. The job requires the use of a number of skills. | 1 2 3 4 5 |

| Specialization | | | | |
|----------------|-----------------|
| 41. The job is highly specialized in terms of purpose, tasks, or activities. | 1 2 3 4 5 |
| 42. The tools, procedures, materials, and so forth used on this job are highly specialized in terms of purpose. | 1 2 3 4 5 |
| 43. The job requires very specialized knowledge and skills. | 1 2 3 4 5 |
| 44. The job requires a depth of knowledge and expertise. | 1 2 3 4 5 |

**Social Characteristics**

| Social Support | | | | |
|----------------|-----------------|
| 45. I have the opportunity to develop close friendships in my job. | 1 2 3 4 5 |
| 46. I have the chance in my job to get to know other people. | 1 2 3 4 5 |
| 47. I have the opportunity to meet with others in my work. | 1 2 3 4 5 |
| 48. My supervisor is concerned about the welfare of the people that work for him/her. | 1 2 3 4 5 |
| 49. People I work with take a personal interest in me. | 1 2 3 4 5 |
| 50. People I work with are friendly. | 1 2 3 4 5 |

| Interdependence/Initiated Interdependence | | | | |
|------------------------------------------|-----------------|
| 51. The job requires me to accomplish my job before others complete their jobs. | 1 2 3 4 5 |
| 52. Other jobs depend directly on my job. | 1 2 3 4 5 |
| 53. Unless my job gets done, other jobs cannot be completed. | 1 2 3 4 5 |

| Interdependence/Received Interdependence | | | | |
|-----------------------------------------|-----------------|
| 54. The job activities are greatly affected by the work of other people. | 1 2 3 4 5 |
| 55. The job depends on the work of many different people for its completion. | 1 2 3 4 5 |
| 56. My job cannot be done unless others do their work. | 1 2 3 4 5 |

| Interaction Outside Organization | | | | |
|-----------------------------------|-----------------|
| 57. The job requires spending a great deal of time with people outside my organization. | 1 2 3 4 5 |
| 58. The job involves interaction with people who are not members of my organization. | 1 2 3 4 5 |
| 59. On the job, I frequently communicate with people who do not work for the same organization as I do. | 1 2 3 4 5 |
| 60. The job involves a great deal of interaction with people outside my organization. | 1 2 3 4 5 |

| Feedback from Others | | | | |
|----------------------|-----------------|
| 61. I receive a great deal of information from my manager and co-workers about my job performance. | 1 2 3 4 5 |
| 62. Other people in the organization, such as managers and co-workers, provide information about the effectiveness (e.g., quality and quantity) of my job performance. | 1 2 3 4 5 |
| 63. I receive feedback on my performance from other people in my organization (such as my manager or co-workers). | 1 2 3 4 5 |

Source: Table adapted from Morgeson and Humphrey (2006). See supporting reference for reliability and validity information. Scores for each approach are calculated by averaging applicable items.

2.2.2 Design Recommendations

Table 2 provides a list of statements that describe recommendations for the motivational approach. It suggests a job should allow a worker autonomy to make decisions about how and when tasks are to be done. A worker should feel his or her work is important to the overall mission of the organization or department. This is often done by allowing a worker to perform a larger unit of work or to perform an entire piece of work from beginning to end. Feedback on job performance should be given to workers from the task itself as well as from the supervisor and others. Workers should be able to use a variety of skills and to personally grow on the job. This approach also considers the social, or people/interaction, aspects of the job; jobs should have opportunities for participation, communication, and recognition. Finally, other human resource systems should contribute to the motivating atmosphere, such as adequate pay, promotion, and job security systems.

2.2.3 Advantages and Disadvantages

The goal of this approach is to enhance psychological meaningfulness of jobs, thus influencing a variety of attitudinal and behavioral outcomes. Table 1 summarizes some of the advantages and disadvantages found in research. Jobs designed according to the motivational approach have more satisfied, motivated, and involved employees who tend to have higher performance and lower absenteeism. Customer service may be improved, because employees take more pride in work and can catch their own errors by performing a larger part of the work. Social impact, social worth, and mere social contact have been shown to have a positive influence on workers’ performance (Grant, 2008; Grant et al., 2007). In a field experiment with community recreation center lifeguards, Grant (2008) demonstrated that task significance operated through their perceptions of social impact and social worth to influence job dedication and helping behavior. As an answer to the rapidly
changing nature of work, researchers have begun to study work design characteristics that could stimulate employee proactiveness. While some characteristics are already embedded within the current models of job design, the approach has led to a few additional characteristics that could prove beneficial in a dynamic work environment. Specifically, both ambiguity and accountability have been suggested to influence employees' proactive behaviors (Grant and Parker, 2009; Staw and Boettger, 1990). In terms of disadvantages, jobs too high on the motivational approach require more training, have greater skill and ability requirements for staffing, and may require higher compensation. Overly motivating jobs may also be so stimulating that workers become predisposed to mental overload, fatigue, errors, and occupational stress.

2.3 Perceptual/Motor Job Design Approach

2.3.1 Historical Development

This approach draws on a scientific discipline which goes by many names, including human factors, human factors engineering, human engineering, man–machine systems engineering, and engineering psychology. It developed from a number of other disciplines, primarily experimental psychology, but also industrial engineering (Meister, 1971). Within experimental psychology, job design recommendations draw heavily from knowledge of human skilled performance (Welford, 1976) and the analysis of humans as information processors (see Chapters 2–4). The main concern of this approach is efficient and safe utilization of humans in human–machine systems, with emphasis on selection, design, and arrangement of system components to take account of both human abilities and limitations (Pearson, 1971). It is more concerned with equipment than psychology and with human abilities than engineering.

This approach received public attention with the Three Mile Island incident where it was concluded that the control room operator job in the nuclear power plant may have placed too many demands on the operator in an emergency situation, thus predisposing errors of judgment (Campion and Thayer, 1987). Government regulations issued since then require nuclear plants to consider “human factors” in their design (U.S. Nuclear Regulatory Commission, 1981). The primary emphasis of this approach is on perceptual and motor abilities of people. (See Chapters 20–22 for more information on equipment design.)

The contextual characteristics of the WDQ reflect the physical and environmental contexts within which work is performed. This was an aspect initially described in the MJDO and subsequently elaborated upon in the WDQ. Many of the contextual characteristics of job design encompass the perceptual–motor and biological/physiological (described in Section 2.4) approaches to job design as addressed in the MJDQ. Contextual characteristics include ergonomics, physical demands, work conditions, and equipment use. The WDQ’s discrimination between contextual characteristics and other forms of motivational characteristics (i.e., task, knowledge, and social characteristics) allows managers to focus specifically on the aspects of work that can produce worker strain or hazardous working conditions while still assessing the motivating aspects of the work. Meta-analytic evidence suggests that the contextual work characteristics addressed in the WDQ explain incremental variance above and beyond that explained by the motivational characteristics (Humphrey et al., 2007).

2.3.2 Design Recommendations

Table 2 provides a list of statements describing important recommendations of the perceptual/motor approach. They refer to either the equipment or environment and to information-processing requirements. Their thrust is to consider mental abilities and limitations of humans such that the attention and concentration requirements of the job do not exceed the abilities of the least capable potential worker. Focus is on the limits of the least capable worker because this approach is concerned with the effectiveness of the total system, which is no better than its “weakest link.” Jobs should be designed to limit the amount of information workers must pay attention to and remember. Lighting levels should be appropriate, displays and controls should be logical and clear, workplaces should be well laid out and safe, and equipment should be easy to use. (See Chapters 56–61 for more information on human factors applications.)

2.3.3 Advantages and Disadvantages

The goals of this approach are to enhance reliability, safety, and positive user reactions. Table 1 summarizes advantages and disadvantages found in research. Jobs designed according to the perceptual/motor approach have lower errors and accidents. Like the mechanistic approach, it reduces mental ability requirements of the job; thus employees may be less stressed and mentally fatigued. It may also create some efficiencies, such as reduced training time and staffing requirements. On the other hand, costs from the excessive use of the perceptual/motor approach can include low satisfaction, low motivation, and boredom due to inadequate mental stimulation. This problem is exacerbated by the fact that designs based on the least capable worker essentially lower a job’s mental requirements.

2.4 Biological Job Design Approach

2.4.1 Historical Development

This approach and the perceptual/motor approach share a joint concern for proper person–machine fit. The major difference is that this approach is more oriented toward biological considerations and stems from such disciplines as work physiology (see Chapter 10), biomechanics (i.e., study of body movements, see Chapter 9), and anthropometry (i.e., study of body sizes, see Chapters 8 and 23). Although many specialists probably practice both approaches together, as is reflected in many texts in the area (Konz, 1983), a split does exist between Americans who are more psychologically oriented and use the title “human factors engineer” and Europeans who are more physiologically oriented and use the title “ergonomist” (Chapanis, 1970). Like the
perceptual–motor approach, the biological approach is concerned with the design of equipment and workplaces as well as the design of tasks (Grandjean, 1980).

2.4.2 Design Recommendations

Table 2 lists important recommendations from the biological approach. This approach tries to design jobs to reduce physical demands to avoid exceeding people’s physical capabilities and limitations. Jobs should not require excessive strength and lifting, and, again, abilities of the least physically able potential worker set the maximum level. Chairs should be designed for good postural support. Excessive wrist movement should be reduced by redesigning tasks and equipment. Noise, temperature, and atmosphere should be controlled within reasonable limits. Proper work–rest schedules should be provided so employees can recuperate from the physical demands.

2.4.3 Advantages and Disadvantages

The goals of this approach are to maintain employees’ comfort and physical well-being. Table 1 summarizes some advantages and disadvantages observed in research. Jobs designed according to this approach require less physical effort, result in less fatigue, and create fewer injuries and aches and pains than jobs low on this approach. Occupational illnesses, such as lower back pain and carpal tunnel syndrome, are fewer on jobs designed with this approach. There may be lower absenteeism and higher job satisfaction on jobs which are not physically arduous. However, a direct cost of this approach may be the expense of changes in equipment or job environments needed to implement the recommendations. At the extreme, costs may include jobs with so few physical demands that workers become drowsy or lethargic, thus reducing performance. Clearly, extremes of physical activity and inactivity should be avoided, and an optimal level of physical activity should be developed.

3 TEAM DESIGN APPROACH

3.1 Historical Development

An alternative to designing work around individual jobs is to design work for teams of workers. Teams can vary a great deal in how they are designed and can conceivably incorporate elements from any of the job design approaches discussed. However, the focus here is on the self-managing, autonomous type of team design approach, which is gaining considerable popularity in organizations and substantial research attention today (Guzzo and Shea, 1992; Hoerr, 1989; Igen et al., 2005; Sundstrom et al., 1990; Swezey and Salas, 1992; Campion et al., 1996; Parker, 2003; LePine et al., 2008). Autonomous work teams derive their conceptual basis from motivational job design and from sociotechnical systems theory, which in turn reflect social and organizational psychology and organizational behavior (Cummings, 1978; Davis, 1971; Davis and Valfer, 1965; Morgeson and Campion, 2003). The Hawthorne studies (Homans, 1950) and European experiments with autonomous work groups (Kelly, 1982; Pasmore et al., 1982) called attention to the benefits of applying work teams in situations other than sports and military settings. Although enthusiasm for the use of teams had waned in the 1960s and 1970s due to research discovering some disadvantages of teams (Buys, 1978; Zander, 1979), the 1980s brought a resurgence of interest in the use of work teams and it has become an extremely popular work design in organizations today (Hackman, 1987). This renewed interest may be due to the cost advantages of having fewer supervisors with self-managed teams or the apparent logic of the benefits of teamwork.

3.2 Design Recommendations

Teams can vary in the degree of authority and autonomy they have (Banker et al., 1996). For example, manager-led teams have responsibility only for the execution of their work. Management designs the work, designs the teams, and provides an organizational context for the teams. However, in autonomous work teams, or self-managing teams, team members design and monitor their own work and performance. They may also design their own team structure (e.g., delineating interrelationships among members) and composition (e.g., selecting members). In such self-designing teams, management is only responsible for the teams’ organizational context (Hackman, 1987). Although team design could incorporate elements of either mechanistic or motivational approaches to design, narrow and simplistic mechanistically designed jobs would be less consistent with other suggested aspects of the team approach to design than motivationally designed jobs. Mechanistically designed jobs would not allow an organization to gain as much of the advantages from placing workers in teams.

Figure 1 and Table 4 provide important recommendations from the self-managing team design approach. Many of the advantages of work teams depend on how teams are designed and supported by their organization. According to the theory behind self-managing team design, decision making and responsibility should be pushed down to the team members (Hackman, 1987). If management is willing to follow this philosophy, teams can provide several additional advantages. By pushing decision making down to the team and requiring consensus, the organization will find greater acceptance, understanding, and ownership of decisions (Porter et al., 1987). The perceived autonomy resulting from making work decisions should be both satisfying and motivating. Thus, this approach tries to design teams so they have a high degree of self-management and all team members participate in decision making.

The team design approach also suggests that the set of tasks assigned to a team should provide a whole and meaningful piece of work (i.e., have task identity as in the motivational approach to job design). This allows team members to see how their work contributes to a whole product or process, which might not be possible with individuals working alone. This can give workers a better idea of the significance of their work and create greater identification with the finished product or service. If team members rotate among a variety of subtasks and cross-train on different operations,

workers should also perceive greater variety in the work (Campion et al., 1994b).

Interdependent tasks, goals, feedback, and rewards should be provided to create feelings of team interdependence among members and focus on the team as the unit of performance, rather than on the individual. It is suggested that team members should be heterogeneous in terms of areas of expertise and background so their varied knowledge, skills, and abilities (KSAs) complement one another. Teams also need adequate training, managerial support, and organizational resources to carry out their tasks. Managers should encourage positive group processes including open communication and cooperation within and between work groups, supportiveness and sharing of the workload among team members, and development of positive team spirit and confidence in the team’s ability to perform effectively.

3.3 Advantages and Disadvantages

Table 5 summarizes advantages and disadvantages of team design relative to individual job design. To begin with, teams designed so members have heterogeneity of KSAs can help team members learn by working with others who have different KSAs. Cross-training on different tasks can occur, and the workforce can become more flexible (Goodman et al., 1986). Teams with heterogeneous KSAs also allow for synergistic combinations of ideas and abilities not possible with individuals working alone, and such teams have generally shown higher performance, especially when task requirements are diverse (Goodman et al., 1986; Shaw, 1983).

Social support can be especially important when teams face difficult decisions and deal with difficult psychological aspects of tasks, such as in military
Table 4 Team Design Measure

*Instructions:* This questionnaire consists of statements about your team and how your team functions as a group. Please indicate the extent to which each statement describes your team by circling a number to the right of each statement. Please use the following scale:

- (5) Strongly agree
- (4) Agree
- (3) Neither agree nor disagree
- (2) Disagree
- (1) Strongly disagree
- () Leave blank if do not know or not applicable

| Self-Management | 1. The members of my team are responsible for determining the methods, procedures, and schedules with which the work gets done. | 1 | 2 | 3 | 4 | 5 |
| 2. My team rather than my manager decides who does what tasks within the team. | 1 | 2 | 3 | 4 | 5 |
| 3. Most work-related decisions are made by the members of my team rather than by my manager. | 1 | 2 | 3 | 4 | 5 |

| Participation | 4. As a member of a team, I have a real say in how the team carries out its work. | 1 | 2 | 3 | 4 | 5 |
| 5. Most members of my team get a chance to participate in decision making. | 1 | 2 | 3 | 4 | 5 |
| 6. My team is designed to let everyone participate in decision making. | 1 | 2 | 3 | 4 | 5 |

| Task Variety | 7. Most members of my team get a chance to learn the different tasks the team performs. | 1 | 2 | 3 | 4 | 5 |
| 8. Most everyone on my team gets a chance to do the more interesting tasks. | 1 | 2 | 3 | 4 | 5 |
| 9. Task assignments often change from day to day to meet the workload needs of the team. | 1 | 2 | 3 | 4 | 5 |

| Task Significance (Importance) | 10. The work performed by my team is important to the customers in my area. | 1 | 2 | 3 | 4 | 5 |
| 11. My team makes an important contribution to serving the company’s customers. | 1 | 2 | 3 | 4 | 5 |
| 12. My team helps me feel that my work is important to the company. | 1 | 2 | 3 | 4 | 5 |

| Task Identity (Mission) | 13. The team concept allows all the work on a given product to be completed by the same set of people. | 1 | 2 | 3 | 4 | 5 |
| 14. My team is responsible for all aspects of a product for its area. | 1 | 2 | 3 | 4 | 5 |
| 15. My team is responsible for its own unique area or segment of the business. | 1 | 2 | 3 | 4 | 5 |

| Task Interdependence (Interdependence) | 16. I cannot accomplish my tasks without information or materials from other members of my team. | 1 | 2 | 3 | 4 | 5 |
| 17. Other members of my team depend on me for information or materials needed to perform their tasks. | 1 | 2 | 3 | 4 | 5 |
| 18. Within my team, jobs performed by team members are related to one another. | 1 | 2 | 3 | 4 | 5 |

| Goal Interdependence (Goals) | 19. My work goals come directly from the goals of my team. | 1 | 2 | 3 | 4 | 5 |
| 20. My work activities on any given day are determined by my team’s goals for that day. | 1 | 2 | 3 | 4 | 5 |
| 21. I do very few activities on my job that are not related to the goals of my team. | 1 | 2 | 3 | 4 | 5 |

| Interdependent Feedback and Rewards (Feedback and Rewards) | 22. Feedback about how well I am doing my job comes primarily from information about how well the entire team is doing. | 1 | 2 | 3 | 4 | 5 |
| 23. My performance evaluation is strongly influenced by how well my team performs. | 1 | 2 | 3 | 4 | 5 |
| 24. Many rewards from my job (pay, promotion, etc.) are determined in large part by my contributions as a team member. | 1 | 2 | 3 | 4 | 5 |

(continued overleaf)
Table 4 (continued)

Heterogeneity (Membership)
25. The members of my team vary widely in their areas of expertise. 1 2 3 4 5
26. The members of my team have a variety of different backgrounds and experiences. 1 2 3 4 5
27. The members of my team have skills and abilities that complement each other. 1 2 3 4 5

Flexibility (Member Flexibility)
28. Most members of my team know each other’s jobs. 1 2 3 4 5
29. It is easy for the members of my team to fill in for one another. 1 2 3 4 5
30. My team is very flexible in terms of membership. 1 2 3 4 5

Relative Size (Size)
31. The number of people in my team is too small for the work to be accomplished. (Reverse scored) 1 2 3 4 5

Preference for Team Work (Team Work Preferences)
32. If given the choice, I would prefer to work as part of a team rather than work alone. 1 2 3 4 5
33. I find that working as a member of a team increases my ability to perform effectively. 1 2 3 4 5
34. I generally prefer to work as part of a team. 1 2 3 4 5

Training
35. The company provides adequate technical training for my team. 1 2 3 4 5
36. The company provides adequate quality and customer service training for my team. 1 2 3 4 5
37. The company provides adequate team skills training for my team (communication, organization, interpersonal, etc.). 1 2 3 4 5

Managerial Support
38. Higher management in the company supports the concept of teams. 1 2 3 4 5
39. My manager supports the concept of teams. 1 2 3 4 5

Communication/Cooperation between Work Groups
40. I frequently talk to other people in the company besides the people on my team. 1 2 3 4 5
41. There is little competition between my team and other teams in the company. 1 2 3 4 5
42. Teams in the company cooperate to get the work done. 1 2 3 4 5

Potency (Spirit)
43. Members of my team have great confidence that the team can perform effectively. 1 2 3 4 5
44. My team can take on nearly any task and complete it. 1 2 3 4 5
45. My team has a lot of team spirit. 1 2 3 4 5

Social Support
46. Being in my team gives me the opportunity to work in a team and provide support to other team members. 1 2 3 4 5
47. My team increases my opportunities for positive social interaction. 1 2 3 4 5
48. Members of my team help each other out at work when needed. 1 2 3 4 5

Workload Sharing (Sharing the Work)
49. Everyone on my team does their fair share of the work. 1 2 3 4 5
50. No one in my team depends on other team members to do the work for them. 1 2 3 4 5
51. Nearly all the members of my team contribute equally to the work. 1 2 3 4 5

Communication/Cooperation within the Work Group
52. Members of my team are very willing to share information with other team members about our work. 1 2 3 4 5
53. Teams enhance the communications among people working on the same product. 1 2 3 4 5
54. Members of my team cooperate to get the work done. 1 2 3 4 5

Source: Adapted from Campion and Medsker (1992).

Squads, medical teams, or police units (Campion and Medsker, 1992). In addition, the simple presence of others can be psychologically arousing. Research has shown that such arousal can have a positive effect on performance when the task is well learned (Zajonc, 1965) and when other team members are perceived as evaluating the performer (Harkins, 1987; Porter et al., 1987). With routine jobs, this arousal effect may counteract boredom and performance decrements (Cartwright, 1968).

Another advantage of teams is that they can increase information exchanged between members through proximity and shared tasks (McGrath, 1984). Increased cooperation and communication within teams can be particularly useful when workers’ jobs are highly interrelated, such as when workers whose tasks come later in the process must depend on the performance of workers whose tasks come earlier or when workers exchange work back and forth among themselves (Mintzberg, 1979; Thompson, 1967).

In addition, if teams are rewarded for team effort, rather than individual effort, members will have an incentive to cooperate with one another (Leventhal, 1976). The desire to maintain power by controlling information may be reduced. More experienced workers may be more willing to train the less experienced when they are not in competition with them. Team design and rewards can also be helpful in situations where it is difficult to measure individual performance or where workers mistrust supervisors’ assessments of performance (Milkovich and Newman, 1993).

Finally, teams can be beneficial if team members develop a feeling of commitment and loyalty to their team (Cartwright, 1968). For workers who do not develop high commitment to their organization or management and who do not become highly involved in their job, work teams can provide a source of commitment. That is, members may feel responsible to attend work, cooperate with others, and perform well because of commitment to their work team, even though they are not strongly committed to the organization or the work itself.

Thus, designing work around teams can provide several advantages to organizations and their workers. Unfortunately, there are also disadvantages to using work teams and situations in which individual-level design is preferable to team design. For example, some individuals may dislike team work and may not have necessary interpersonal skills or desire to work in a team. When selecting team members, one has the additional requirement of selecting workers to fit the team as well as the job. (Section 4.3 provides more information on the selection of team members; see also Chapter 16 for general information on personnel selection.)

Individuals can experience less autonomy and less personal identification when working on a team. Designing work around teams does not guarantee workers greater variety, significance, and identity. If members within the team do not rotate among tasks or if some members are assigned exclusively to less desirable tasks, not all members will benefit from team design. Members can still have fractionated, demotivating jobs.

Team work can also be incompatible with cultural norms. The United States has a very individualistic culture (Hofstede, 1980). Applying team methods that have been successful in collectivistic societies like Japan may be problematic in the United States. In addition,
Some advantages of team design can create disadvantages as well. First, though team rewards can increase communication and cooperation and reduce competition within a team, they may cause greater competition and reduced communication between teams. If members identify too strongly with a team, they may not realize when behaviors that benefit the team detract from organizational goals and create conflicts detrimental to productivity. Increased communication within teams may not always be task relevant either. Teams may spend work time socializing. Team decision making can take longer than individual decision making, and the need for coordination within teams can be time consuming.

Decision making and creativity can also be inhibited by team processes. When teams become highly cohesive, they may become so alike in their views that they develop “groupthink” (Janis, 1972). When groupthink occurs, teams tend to underestimate their competition, fail to adequately critique fellow team members’ suggestions, not appraise alternatives adequately, and fail to work out contingency plans. In addition, team pressures distort judgments. Decisions may be based more on persuasiveness of dominant individuals or the power of majorities, rather than on the quality of decisions. Research has found a tendency for team judgments to be more extreme than the average of individual members’ predecision judgments (Janis, 1972; McGrath, 1984; Morgeson and Campion, 1997). Although evidence shows highly cohesive teams are more satisfied with their teams, cohesiveness is not necessarily related to high productivity. Whether cohesiveness is related to performance depends on a team’s norms and goals. If a team’s norm is to be productive, cohesiveness will enhance productivity; however, if the norm is not one of commitment to productivity, cohesiveness can have a negative influence (Zajonc, 1965). The use of teams and team-level rewards can also decrease the motivating power of evaluation and reward systems. If team members are not evaluated for individual performance, do not believe their output can be distinguished from the team’s, or do not perceive a link between their personal performance and outcomes, social loafing (Harkins, 1987) can occur. In such situations, teams do not perform up to the potential expected from combining individual efforts.

Finally, teams may be less flexible in some respects because they are more difficult to move or transfer as a unit than individuals (Sundstrom et al., 1990). Turnover, replacements, and employee transfers may disrupt teams. And members may not readily accept new members.

Thus, whether work teams are advantageous depends to a great extent on the composition, structure, reward systems, environment, and task of the team. Table 6 presents questions that can help determine whether work should be designed around teams rather than individuals.

Source: Table adapted from Campion and Medsker (1992). Affirmative answers support the use of team job design.

The more questions answered in the affirmative, the more likely teams are to be beneficial. If one chooses to design work around teams, suggestions for designing effective teams are presented in Section 4.3.
According to Davis and Wacker (1982), the process of redesigning existing jobs is much the same as designing original jobs with two additions. First, existing job incumbents must be involved. Second, more attention needs to be given to implementation issues. Those involved in the implementation must feel ownership of and commitment to the change and believe the redesign represents their own interests.

Potential Steps to Follow Along with the steps discussed above, a redesign project should also include the following five steps:

1. Measuring Design of Existing Jobs or Teams. The questionnaire methodology and other analysis tools described in Section 5 may be used to measure current jobs or teams.
2. Diagnosing Potential Design Problems. Based on data collected in step 1, the current design is analyzed for potential problems. The task force and employee involvement are important. Focused team meetings are a useful vehicle for identifying and evaluating problems.
3. Determining Job or Team Design Changes. Changes will be guided by project goals, problems identified in step 2, and one or more of the approaches to work design. Often several potential changes are generated and evaluated. Evaluation of alternative changes may involve consideration of advantages and disadvantages identified in previous research (see Table 1) and opinions of engineers, managers, and employees.
4. Making Design Changes. Implementation plans should be developed in detail along with back-up plans in case there are difficulties with the new design. Communication and training are keys to implementation. Changes might also be pilot tested before widespread implementation.
5. Conducting Follow-Up Evaluation. Evaluating the new design after implementation is probably the most neglected part of the process in most applications. The evaluation might include the collection of design measurements on the redesigned jobs/teams using the same instruments as in step 1. Evaluation may also be conducted on outcomes, such as employee satisfaction, error rates, and training time (Table 1). Scientifically valid evaluations require experimental research strategies with control groups. Such studies may not always be possible in organizations, but often quasi-experimental and other field research designs are possible (Cook and Campbell, 1979). Finally, the need for adjustments is identified through the follow-up evaluation. (For examples of evaluations, see Section 5.8 and Campion and McClelland, 1991, 1993.)
4.1.2 Individual Differences Among Workers

It is a common observation that not all employees respond the same to the same job. Some people on a job have high satisfaction, whereas others on the same job have low satisfaction. Clearly, there are individual differences in how people respond to work. Considerable research has looked at individual differences in reaction to the motivational design approach. It has been found that some people respond more positively than others to highly motivational work. These differences are generally viewed as differences in needs for personal growth and development (Hackman and Oldham, 1980).

Using the broader notion of preferences/tolerances for types of work, the consideration of individual differences has been expanded to all four approaches to job design (Campion, 1988; Campion and McClelland, 1991) and to the team design approach (Campion et al., 1993; Campion et al., 1996). Table 7 provides scales that can be used to determine job incumbents’ preferences/tolerances. These scales can be administered in the same manner as the questionnaire measures of job and team design discussed in Section 5.

Although consideration of individual differences is encouraged, there are often limits to which such differences can be accommodated. Jobs or teams may have

Preferences/Tolerances for Mechanistic Design

1. I have a high tolerance for routine work. 1 2 3 4 5
2. I prefer to work on one task at a time. 1 2 3 4 5
3. I have a high tolerance for repetitive work. 1 2 3 4 5
4. I prefer work that is easy to learn. 1 2 3 4 5

Preferences/Tolerances for Motivational Design

5. I prefer highly challenging work that taxes my skills and abilities. 1 2 3 4 5
6. I have a high tolerance for mentally demanding work. 1 2 3 4 5
7. I prefer work that gives a great amount of feedback as to how I am doing. 1 2 3 4 5
8. I prefer work that regularly requires the learning of new skills. 1 2 3 4 5
9. I prefer work that requires me to develop my own methods, procedures, goals, and schedules. 1 2 3 4 5
10. I prefer work that has a great amount of variety in duties and responsibilities. 1 2 3 4 5

Preferences/Tolerances for Perceptual/Motor Design

11. I prefer work that is very fast paced and stimulating. 1 2 3 4 5
12. I have a high tolerance for stressful work. 1 2 3 4 5
13. I have a high tolerance for complicated work. 1 2 3 4 5
14. I have a high tolerance for work where there are frequently too many things to do at one time. 1 2 3 4 5

Preferences/Tolerances for Biological Design

15. I have a high tolerance for physically demanding work. 1 2 3 4 5
16. I have a fairly high tolerance for hot, noisy, or dirty work. 1 2 3 4 5
17. I prefer work that gives me some physical exercise. 1 2 3 4 5
18. I prefer work that gives me some opportunities to use my muscles. 1 2 3 4 5

Preferences/Tolerances for Team Work

19. If given the choice, I would prefer to work as part of a team rather than work alone. 1 2 3 4 5
20. I find that working as a member of a team increases my ability to perform effectively. 1 2 3 4 5
21. I generally prefer to work as part of a team. 1 2 3 4 5

Source: Table adapted from Campion (1988) and Campion et al. (1993).

Note: See reference for reliability and validity information. Scores for each preference/tolerance are calculated by averaging applicable items. Interpretations differ slightly across the scales. For the mechanistic and motivational designs, higher scores suggest more favorable reactions from incumbents to well-designed jobs. For the perceptual/motor and biological approaches, higher scores suggest less unfavorable reactions from incumbents to poorly designed jobs.
to be designed for people who are not yet known or who differ in their preferences. Fortunately, although evidence indicates individual differences moderate reactions to the motivational approach (Fried and Ferris, 1987), the differences are of degree but not direction. That is, some people respond more positively than others to motivational work, but few respond negatively. It is likely that this also applies to the other design approaches.

4.1.3 Some Basic Choices

Hackman and Oldham (1980) have provided five strategic choices that relate to implementing job redesign. The note that little research exists indicating the exact consequences of each choice, and correct choices may differ by organization. The basic choices are:

1. Individual versus Team Designs for Work. An initial decision is to either enrich individual jobs or create teams. This also includes consideration of whether any redesign should be undertaken and its likelihood of success.
2. Theory Based versus Intuitive Changes. This choice was basically defined as the motivational (theory) approach versus no particular (atheoretical) approach. In the present chapter, this choice may be better framed as choosing among the four approaches to job design. However, as argued earlier, consideration of only one approach may lead to some costs or additional benefits being ignored.
3. Tailored versus Broadside Installation. This choice is between tailoring changes to individuals and making the changes for all in a given job.
4. Participative versus Top-Down Change Processes. The most common orientation is that participative is best. However, costs of participation include the time involved and incumbents’ possible lack of a broad knowledge of the business.
5. Consultation versus Collaboration with Stakeholders. The effects of job design changes often extend far beyond the individual incumbent and department. For example, a job’s output may be an input to a job elsewhere in the organization. The presence of a union also requires additional collaboration. Depending on considerations, participation of stakeholders may range from no involvement through consultation to full collaboration.

4.1.4 Overcoming Resistance to Change in Redesign Projects

Resistance to change can be a problem in any project involving major changes (Morgeson et al., 1997). Failure rates of new technology implementations demonstrate a need to give more attention to the human aspects of change projects. This concern has also been reflected in the area of participatory ergonomics, which encourages the use of participatory techniques when undertaking an ergonomic intervention (Wilson and Haines, 1997). It has been estimated that between 50 and 75% of newly implemented manufacturing technologies in the United States have failed, with a disregard for human and organizational issues considered to be a bigger cause for the failures than technical problems (Majchrzak, 1988; Turnage, 1990). The number one obstacle to implementation was considered to be human resistance to change (Hyer, 1984).

Based on the work of Majchrzak (1988), Gallagher and Knight (1986), and Turnage (1990), guidelines for reducing resistance to change include the following:

1. Involves workers in planning the change. Workers should be informed of changes in advance and involved in the process of diagnosing problems and developing solutions. Resistance is decreased if participants feel the project is their own and not imposed from outside and if the project is adopted by consensus.
2. Top management should strongly support the change. If workers feel management is not strongly committed, they are less likely to take the project seriously.
3. Create change consistent with worker needs and existing values. Resistance is less if change is seen to reduce present burdens, offer interesting experience, and not threaten worker autonomy or security or be inconsistent with other goals and values in the organization. Workers need to see the advantages to them of the change. Resistance is less if proponents of change can empathize with opponents (recognize valid objections and relieve unnecessary fears).
4. Create an environment of open, supportive communication. Resistance will be lessened if participants experience support and have trust in each other. Resistance can be reduced if misunderstandings and conflicts are expected as natural to the innovation process. Provision should be made for clarification.
5. Allow for flexibility. Resistance is reduced if the project is kept open to revision and reconsideration with experience.

4.2 Implementation Advice for Job Design and Redesign

4.2.1 Methods for Combining Tasks

In many cases, designing jobs is largely a function of combining tasks. Some guidance can be gained by extrapolating from specific design recommendations in Table 2. For example, variety in the motivational approach can be increased by simply combining different tasks in the same job. Conversely, specialization from the mechanistic approach can be increased by only including very similar tasks in the same job. It is also possible when designing jobs to first generate alternative task combinations, then evaluate them using the design approaches in Table 2.

A small amount of research within the motivational approach has focused explicitly on predicting relationships between combinations of tasks and the design of resulting jobs (Wong, 1989; Wong and Campion, 1991). This research suggests that a job’s motivational quality
is a function of three task-level variables, as illustrated in Figure 2.

1. **Task Design.** The higher the motivational quality of individual tasks, the higher the motivational quality of a job. Table 2 can be used to evaluate individual tasks; then motivational scores for individual tasks can be summed together. Summing is recommended rather than averaging because both the motivational quality of the tasks and the number of tasks are important in determining a job’s motivational quality (Globerson and Crossman, 1976).

2. **Task Interdependence.** Interdependence among tasks has been shown to be positively related to motivational value up to some moderate point; beyond that point increasing interdependence has been shown to lead to lower motivational value. Thus, for motivational jobs, the total amount of interdependence among tasks should be kept at a moderate level. Both complete independence and excessively high interdependence should be avoided. Table 8 contains the dimension of task interdependence and provides a questionnaire to measure it. Table 8 can be used to judge the interdependence of each pair of tasks that are being evaluated for inclusion in a job.

3. **Task Similarity.** Similarity among tasks may be the oldest rule of job design, but beyond a moderate level, it tends to decrease a job’s motivational value. Thus, to design motivational jobs, high levels of similarity should be avoided. Similarity at the task pair level can be judged in much the same manner as interdependence by using dimensions in Table 8 (see the note to Table 8).

### 4.2.2 Trade-Offs among Job Design Approaches

Although one should strive to construct jobs that are well designed on all the approaches, it is clear design approaches conflict. As Table 1 illustrates, benefits of some approaches are costs of others. No one approach satisfies all outcomes. The greatest potential conflicts are between the motivational and the mechanistic and perceptual/motor approaches. They produce nearly opposite outcomes. The mechanistic and perceptual/motor approaches recommend jobs that are simple, safe, and reliable, with minimal mental demands on workers. The motivational approach encourages more complicated and stimulating jobs, with greater mental demands. The team approach is consistent with the motivational approach and therefore also may conflict with the mechanistic and perceptual/motor approaches.

Because of these conflicts, trade-offs may be necessary. Major trade-offs will be in the mental demands created by the alternative design strategies. Making jobs more mentally demanding increases the likelihood of achieving workers’ goals of satisfaction and motivation but decreases the chances of reaching the organization’s goals of reduced training, staffing costs, and errors. Which trade-offs will be made depends on outcomes one prefers to maximize. Generally, a compromise may be optimal.

Trade-offs may not always be needed, however. Jobs can often be improved on one approach while still maintaining their quality on other approaches. For example, in one redesign study, the motivational approach was applied to clerical jobs to improve employee satisfaction and customer service (Campion and McClelland, 1991). Expected benefits occurred along with some expected costs (e.g., increased training and compensation requirements), but not all potential costs occurred (e.g., quality and efficiency did not decrease).

In another redesign study, Morgeson and Campion (2002) sought to increase both satisfaction and efficiency in jobs at a pharmaceutical company. They found that when jobs were designed to increase only satisfaction or only efficiency, the common trade-offs were present (e.g., increased or decreased satisfaction, training requirements). When jobs were designed to increase both satisfaction and efficiency, however, these trade-offs were reduced. They suggested that a work design process that explicitly considers both motivational and mechanistic aspects of work is key to avoiding the trade-offs.

Another strategy for minimizing trade-offs is to avoid design decisions that influence the mental demands of jobs. An example of this is to enhance motivational design by focusing on social aspects (e.g., communication, participation, recognition, feedback). These design features can be raised without incurring costs of increased mental demands. Moreover, many of these features are under the direct control of managers.

The independence of the biological approach provides another opportunity to improve design without incurring trade-offs with other approaches. One can reduce physical demands without affecting mental demands of a job. Of course, the cost of equipment may need to be considered.

Adverse effects of trade-offs can often be reduced by avoiding designs that are extremely high or low on any approach. Or, alternatively, one might require minimum acceptable levels on each approach. Knowing all approaches and their corresponding outcomes will

---

Table 8 Dimensions of Task Interdependence

Instructions: Indicate the extent to which each statement is descriptive of the pair of tasks using the scale below. Circle answers to the right of each statement. Scores are calculated by averaging applicable items.

Please use the following scale:

(5) Strongly agree
(4) Agree
(3) Neither agree nor disagree
(2) Disagree
(1) Strongly disagree
() Leave blank if do not know or not applicable

Inputs of the Tasks
1. Materials/supplies: One task obtains, stores, or prepares the materials or supplies necessary to perform the other task. 1 2 3 4 5
2. Information: One task obtains or generates information for the other task. 1 2 3 4 5
3. Product/service: One task stores, implements, or handles the products or services produced by the other task. 1 2 3 4 5

Processes of the Tasks
4. Input–output relationship: The products (or outputs) of one task are the supplies (or inputs) necessary to perform the other task. 1 2 3 4 5
5. Method and procedure: One task plans the procedures or work methods for the other task. 1 2 3 4 5
6. Scheduling: One task schedules the activities of the other task. 1 2 3 4 5
7. Supervision: One task reviews or checks the quality of products or services produced by the other task. 1 2 3 4 5
8. Sequencing: One task needs to be performed before the other task. 1 2 3 4 5
9. Time sharing: Some of the work activities of the two tasks must be performed at the same time. 1 2 3 4 5
10. Support service: The purpose of one task is to support or otherwise help the other task get performed. 1 2 3 4 5
11. Tools/equipment: One task produces or maintains the tools or equipment used by the other task. 1 2 3 4 5

Outputs of the Tasks
12. Goal: One task can only be accomplished when the other task is properly performed. 1 2 3 4 5
13. Performance: How well one task is performed has a great impact on how well the other task can be performed. 1 2 3 4 5
14. Quality: The quality of the product or service produced by one task depends on how well the other task is performed. 1 2 3 4 5

Note: The task similarity measure contains 10 comparable items (excluding items 4, 6, 8, 9, and 14 and including an item on customer/client). Scores for each dimension are calculated by averaging applicable items.

help one make more informed decisions and avoid unanticipated consequences.

4.2.3 Other Implementation Advice for Job Design and Redesign

Griffin (1982) provides advice geared toward managers considering a job redesign intervention in their area. He notes that managers may also rely on consultants, task forces, or informal discussion groups. Griffin suggests nine steps:

1. Recognition of a need for change
2. Selection of job redesign as a potential intervention
3. Diagnosis of the work system and content on the following factors:
   a. Existing jobs
   b. Existing workforce
   c. Technology
   d. Organization design
   e. Leader behaviors
   f. Team and social processes
4. Cost/benefit analysis of proposed changes
5. Go/no-go decision
6. Establishment of a strategy for redesign
7. Implementation of the job changes
8. Implementation of any needed supplemental changes
9. Evaluation of the redesigned jobs
Recently, researchers have begun to study the manner in which employees are proactive actors in the job design process. Employees can either actively craft or change their jobs or they can negotiate idiosyncratic deals that alter the design of their work (Wrzesniewski and Dutton, 2001; Grant and Parker, 2009; Rousseau et al., 2006; Hornung et al., 2008). An idiosyncratic deal is a formal agreement that an employee and his or her manager or organization come to regarding the individual’s work which creates a difference in the characteristics of the employee’s work from the characteristics of the work of employees in a similar position. These types of deals represent formal individualized work design arrangements.

Job crafting differs from traditional job design as it describes the changes that employees make to their jobs. While traditional job design is implemented by a manager or an organization, job crafting refers to the informal changes to task or social characteristics that employees make to their work. The implications of these behaviors are that employees will informally change the design of their work. Being informal, they often go undetected and can be difficult for a manager to control. Managers should both recognize that these changes occur and design employees’ work with the understanding that the design of the work can and probably will be altered to some degree by the employee.

4.3 Implementation Advice for Team Design

4.3.1 Deciding on Team Composition

Research encourages heterogeneous teams in terms of skills, personality, and attitudes because it increases the range of competencies in teams (Gladstein, 1984) and is related to effectiveness (Campion et al., 1996). However, homogeneity is preferred if team morale is the main criterion, and heterogeneous attributes must be complementary if they are to contribute to effectiveness. Heterogeneity for its own sake is unlikely to enhance effectiveness (Campion et al., 1993). Another composition characteristic of effective teams is whether members have flexible job assignments (Campion et al., 1993; Sundstrom et al., 1990). If members can perform different jobs, effectiveness is enhanced because they can fill in as needed.

A third important aspect of composition is team size. Evidence suggests the importance of optimally matching team size to team tasks to achieve high performance and satisfaction. Teams need to be large enough to accomplish work assigned to them but may be dysfunctional when too large due to heightened coordination needs (O’Reilly and Roberts, 1977; Steiner, 1972) or increased social loafing (McGrath, 1984; Wicker et al., 1976). Thus, groups should be staffed to the smallest number needed to do the work (Goodman et al., 1986; Hackman, 1987; Sundstrom et al., 1990).

4.3.2 Selecting Team Members

With team design, interpersonal demands appear to be much greater than with traditional individual-based job design (Lawler, 1986). A team-based setting highlights the importance of employees being capable of interacting in an effective manner with peers because the amount of interpersonal interactions required is higher in teams (Stevens and Campion, 1994a,b, 1999). Team effectiveness can depend heavily on members’ “interpersonal competence” or their ability to successfully maintain healthy working relationships and react to others with respect for their viewpoints (Perkins and Abramis, 1990). There is a greater need for team members to be capable of effective interpersonal communication, collaborative problem solving, and conflict management (Stevens and Campion, 1994a,b, 1999).

The process of employment selection for team members places greater stress on adequately evaluating interpersonal competence than is normally required in the selection of workers for individual jobs. To create a selection instrument for evaluating potential team members’ ability to work successfully in teams, Stevens and Campion (1994a,b) reviewed literature in areas of sociotechnical systems theory (e.g., Cummings, 1978; Wall et al., 1986), organizational behavior (e.g., Hackman, 1987; Shea and Guzzo, 1987; Sundstrom et al., 1990), industrial engineering (e.g., Davis and Wacker, 1987; Majchrzak, 1988), and social psychology (e.g., McGrath, 1984; Steiner, 1972) to identify relevant KSAs. Table 9 shows the 14 KSAs identified as important for teamwork.

These KSAs have been used to develop a 35-item, multiple-choice employment test which was validated in two studies to determine how highly related it was to team members’ job performance (Stevens and Campion, 1999). The job performance of team members in two different companies was rated by both supervisors and co-workers. Correlations between the test and job performance ratings were significantly high, with some correlations exceeding 0.50. The test was also able to add to the ability to predict job performance beyond that provided by a large battery of traditional employment aptitude tests. Thus, these findings provide support for the value of the teamwork KSAs and a selection test based on them (Stevens and Campion, 1994a). Table 10 shows some example items from the test.

Aside from written tests, there may be other ways teamwork KSAs could be measured for purposes of selection. For example, interviews may be especially suited to measuring interpersonal attributes (e.g., Posthuma et al., 2002). There is evidence that a structured interview specifically designed to measure social (i.e., nontechnical) KSAs can have validity with job performance and predict incrementally beyond traditional employment tests (Campion et al., 1994a).

Assessment center techniques might also lend themselves to measuring teamwork KSAs. Group exercises have been used to measure leadership and other social skills with good success (Gaugler et al., 1987). It is likely that existing team exercises, such as group problem-solving tasks, could also be modified to score teamwork KSAs.

Selection techniques using biodata may be another way to measure teamwork KSAs. Many items in biodata instruments reflect previous life experiences of a social nature, and recruiters interpret biodata information on applications and resumes as reflecting attributes such as interpersonal skills (Brown and Campion, 1994).
Table 9 Knowledge, Skill, and Ability (KSA) Requirements for Teamwork

I. Interpersonal KSAs
   A. Conflict Resolution KSAs
      1. The KSA to recognize and encourage desirable but discourage undesirable team conflict.
      2. The KSA to recognize the type and source of conflict confronting the team and to implement an appropriate conflict resolution strategy.
      3. The KSA to employ an integrative (win–win) negotiation strategy rather than the traditional distributive (win–lose) strategy.
   B. Collaborative Problem-Solving KSAs
      4. The KSA to identify situations requiring participative group problem solving and to utilize the proper degree and type of participation.
      5. The KSA to recognize the obstacles to collaborative group problem solving and implement appropriate corrective actions.
   C. Communication KSAs
      6. The KSA to understand communication networks and to utilize decentralized networks to enhance communication where possible.
      7. The KSA to communicate openly and supportively, that is, to send messages which are (a) behavior or event oriented, (b) congruent, (c) validating, (d) conjunctive, and (e) owned.
      8. The KSA to listen nonevaluatively and to appropriately use active listing techniques.
      9. The KSA to recognize consonance between nonverbal and verbal messages and to recognize and interpret the nonverbal messages of others.
     10. The KSA to engage in ritual greetings and small talk and a recognition of their importance.

II. Self-Management KSAs
   D. Goal Setting and Performance Management KSAs
      11. The KSA to help establish specific, challenging, and accepted team goals.
      12. The KSA to monitor, evaluate, and provide feedback on both overall team performance and individual team member performance.
   E. Planning and Task Coordination KSAs
      13. The KSA to coordinate and synthesize activities, information, and task interdependencies between team members.
      14. The KSA to help establish task and role expectations of individual team members and to ensure proper balancing of workload in the team.

Table 10 Example Items from the Teamwork KSA Test

1. Suppose you find yourself in an argument with several co-workers who should do a very disagreeable but routine task. Which of the following would likely be the most effective way to resolve this situation?
   A. Have your supervisor decide, because this would avoid any personal bias.
   *B. Arrange for a rotating schedule so everyone shares the chore.
   C. Let the workers who show up earliest choose on a first come, first served basis.
   D. Randomly assign a person to do the task and don’t change it.

2. Your team wants to improve the quality and flow of the conversations among its members. Your team should:
   A. Use comments that build upon and connect to what others have said.
   *B. Set up a specific order for everyone to speak and then follow it.
   C. Let team members with more to say determine the direction and topic of conversation.
   D. Do all of the above.

3. Suppose you are presented with the following types of goals. You are asked to pick one for your team to work on. Which would you choose?
   A. An easy goal to ensure the team reaches it, thus creating a feeling of success.
   B. A goal of average difficulty so the team will be somewhat challenged but successful without too much effort.
   *C. A difficult and challenging goal that will stretch the team to perform at a high level but one that is attainable so that effort will not be seen as futile.
   D. A very difficult or even impossible goal so that even if the team falls short, it will at least have a very high target to aim for.

Note: asterisk indicates correct answer.

A biodata measure developed to focus on teamwork KSAs might include items on teamwork in previous jobs, team experiences in school (e.g., college clubs, class projects), and recreational activities of a team nature (e.g., sports teams and social groups).

4.3.3 Designing the Teams’ Jobs

This aspect of team design involves team characteristics derived from the motivational job design approach. The main distinction is in level of application rather than content (Campion and Medsker, 1992; Shea and Guzzo, 1987; Wall et al., 1986). All the job characteristics of the motivational approach to job design can be applied to team design.

One such characteristic is self-management, which is the team-level analogy to autonomy at the individual job level. It is central to many definitions of effective work
teams (e.g., Cummings, 1978, 1981; Hackman, 1987). A related characteristic is participation. Regardless of management involvement in decision making, teams can still be distinguished in terms of the degree to which all members are allowed to participate in decisions (McGrath, 1984, Porter et al., 1987). Self-management and participation are presumed to enhance effectiveness by increasing members’ sense of responsibility and ownership of the work. These characteristics may also enhance decision quality by increasing relevant information and by putting decisions as near as possible to the point of operational problems and uncertainties.

Other important characteristics are task variety, task significance, and task identity. Variety motivates by allowing members to use different skills (Hackman, 1987) and by allowing both interesting and dull tasks to be shared among members (Davis and Wacker, 1987). Task significance refers to the perceived significance of the consequences of the team’s work, for either others inside the organization or its customers. Task identity (Hackman, 1987), or task differentiation (Cummings, 1978), refers to the degree to which the team completes a whole and meaningful piece of work. These suggested characteristics of team design have been found to be positively related to team productivity, team member satisfaction, and managers’ and employees’ judgments of their teams’ performance (Campion et al., 1993, 1995).

4.3.4 Developing Interdependent Relations

Interdependence is often the reason teams are formed (Mintzberg, 1979) and is a defining characteristic of teams (Salas et al., 1992; Wall et al., 1986). Interdependence has been found to be related to team members’ satisfaction and team productivity and effectiveness (Campion et al., 1993, 1995).

One form of interdependence is task interdependence. Team members interact and depend on one another to accomplish their work. Interdependence varies across teams, depending on whether the work flow in a team is pooled, sequential, or reciprocal (Thompson, 1967). Interdependence among tasks in the same job (Wong and Campion, 1991) or between jobs (Kiggundu, 1983) has been related to increased motivation. It can also increase team effectiveness because it enhances the sense of responsibility for others’ work (Kiggundu, 1983) or because it enhances the reward value of a team’s accomplishments (Shea and Guzzo, 1987).

Another form of interdependence is goal interdependence. Goal setting is a well-documented, individual-level performance improvement technique (Locke and Latham, 1990). A clearly defined mission or purpose is considered to be critical to team effectiveness (Campion et al., 1993, 1995; Davis and Wacker, 1987; Hackman, 1987; Sundstrom et al., 1990). Its importance has also been shown in empirical studies on teams (e.g., Buller and Bell, 1986; Woodman and Sherwood, 1980). Not only should goals exist for teams, but individual members’ goals must be linked to team goals to be maximally effective.

Finally, interdependent feedback and rewards have also been found to be important for team effectiveness and team member satisfaction (Campion et al., 1993, 1995). Individual feedback and rewards should be linked to a team’s performance in order to motivate team-oriented behavior. This characteristic is recognized in many theoretical treatments (e.g., Hackman, 1987; Leventhal, 1976; Steiner, 1972; Sundstrom et al., 1990) and research studies (e.g., Pasmor et al., 1982; Wall et al., 1986).

4.3.5 Creating the Organizational Context

Organizational context and resources are considered in all recent models of work team effectiveness (e.g., Guzzo and Shea, 1992; Hackman, 1987). One important aspect of context and resources for teams is adequate training. Training is an extensively researched determinant of team performance (for reviews see Dyer, 1984; Salas et al., 1992), and training is included in most interventions (e.g., Pasmor et al., 1982; Wall et al., 1986). Training is related to team members’ satisfaction and managers’ and employees’ judgments of their teams’ effectiveness (Campion et al., 1993, 1995).

Training content often includes team philosophy, group decision making, and interpersonal skills as well as technical knowledge. Many team-building interventions focus on aspects of team functioning that are related to the teamwork KSAs shown in Table 9. A recent review of this literature divided such interventions into four approaches (Tannenbaum et al., 1992)—goal setting, interpersonal role, and problem solving—which are similar to the teamwork KSA categories. Thus, these interventions could be viewed as training programs on teamwork KSAs. Reviews indicate that the evidence for the effectiveness of this training appears positive despite the methodological limitations that plague this research (Buller and Bell, 1986; Tannenbaum et al., 1992; Woodman and Sherwood, 1980). It appears that workers can be trained in teamwork KSAs. (See Chapter 16 for more information on team training.)

Regarding how such training should be conducted, there is substantial guidance on training teams in the human factors and military literatures (Dyer, 1984; Salas et al., 1992; Swezy and Salas, 1992). Because these topics are thoroughly addressed in the cited sources, they will not be reviewed here.

Managers of teams also need to be trained in teamwork KSAs, regardless of whether the teams are manager led or self-managed. The KSAs are needed for interacting with employee teams and for participating on management teams. It has been noted that managers of teams, especially autonomous work teams, need to develop their employees (Cummings, 1978; Hackman and Oldham, 1980; Manz and Sims, 1987). Thus, training must ensure not only that managers possess teamwork KSAs but also that they know how to train employees on these KSAs.

Managerial support is another contextual characteristic (Morgeson, 2005). Management controls resources (e.g., material and information) required to make team functioning possible (Shea and Guzzo, 1987), and an organization’s culture and top management must support
the use of teams (Sundstrom et al., 1992). Teaching facilitative leadership to managers is often a feature of team interventions (Pasmore et al., 1982). Finally, communication and cooperation between teams are contextual characteristics because they are often the responsibility of managers. Supervising team boundaries (Cummings, 1978) and externally integrating teams with the rest of the organization (Sundstrom et al., 1990) enhance effectiveness. Research indicates that managerial support and communication and cooperation between work teams are related to team productivity and effectiveness and to team members’ satisfaction with their work (Campion et al., 1993, 1995).

4.3.6 Developing Effective Team Process

Process describes those things that go on in the group that influence effectiveness. One process characteristic is potency, or the belief of a team that it can be effective (Guzzo and Shea, 1992; Shea and Guzzo, 1987). It is similar to the lay-term “team spirit.” Hackman (1987) argues that groups with high potency are more committed and willing to work hard for the group, and evidence indicates that potency is highly related to team members’ satisfaction with work, team productivity, and members’ and managers’ judgments of their teams’ effectiveness (Campion et al., 1993, 1995).

Another process characteristic found to be related to team satisfaction, productivity, and effectiveness is social support (Campion et al., 1993, 1995). Effectiveness can be enhanced when members help each other and have positive social interactions. Like social facilitation (Harkins, 1987; Zajonc, 1965), social support can be arousing and may enhance effectiveness by sustaining effort on mundane tasks.

Another process characteristic related to satisfaction, productivity, and effectiveness is workload sharing (Campion et al., 1993, 1995). Workload sharing enhances effectiveness by preventing social loafing or free riding (Harkins, 1987). To enhance sharing, group members should believe their individual performance can be distinguished from the group’s and that there is a link between their performance and outcomes.

Finally, communication and cooperation within the work group are also important to team effectiveness, productivity, and satisfaction (Campion et al., 1993, 1995). Management should help teams foster open communication, supportiveness, and discussions of strategy. Informal, rather than formal, communication channels and mechanisms of control should be promoted to ease coordination (Bass and Kluebeck, 1952; Majchrzak, 1988). Managers should encourage self-evaluation, self-observation, self-reinforcement, self-management, and self-goal setting by teams. Self-criticism for purposes of recrimination should be discouraged (Manz and Sims, 1987).

Recent meta-analytic evidence suggests that numerous team processes are related to both team performance and member satisfaction (LePine et al., 2008). Many of these processes can be grouped into three categories. Transition processes are team actions that occur after one team task has ended and before the next begins and include actions such as mission analysis, goal specification, and strategy formulation/planning. Action processes are team activities that occur during the completion of a task. The four types of action processes include monitoring progress toward goals, systems monitoring (assessing resources and environmental factors that could influence goal accomplishment), team monitoring and backup behavior (team members assisting each other in their individual tasks), and coordination. Finally, team activities geared toward maintaining the team’s interpersonal relationships are called interpersonal processes and include conflict management, motivating/confidence building, and affect management (e.g., emotional balance, togetherness, and coping with demands/frustrations). The results suggest that there are specific team processes that occur at different stages of task completion, and the occurrence, or lack thereof, of these processes has an impact on both the teams’ performance and team members’ satisfaction (LePine et al. 2008).

5 MEASUREMENT AND EVALUATION OF JOB AND TEAM DESIGN

The purpose of an evaluation study for either a job or team design is to provide an objective evaluation of success and to create a tracking and feedback system to make adjustments during the course of the design project. An evaluation study can provide objective data to make informed decisions, help tailor the process to the organization, and give those affected by the design or redesign an opportunity to provide input (see Morgeson and Campion, 2002). An evaluation study should include measures that describe the characteristics of the jobs or teams so that it can be determined whether or not jobs or teams ended up having the characteristics they were intended to have. An evaluation study should also include measures of effectiveness outcomes an organization hoped to achieve with a design project.

Measures of effectiveness could include such subjective outcomes as employee job satisfaction or employee, manager, or customer perceptions of effectiveness. Measures of effectiveness should also include objective outcomes such as cost, productivity, rework/scrap, turnover, accident rates, or absenteeism. Additional information on measurement and evaluation of such outcomes can be found in Part 6 of this handbook.

5.1 Using Questionnaires to Measure Job and Team Design

One way to measure job or team design is by using questionnaires or checklists. This method of measuring job or team design is highlighted because it has been used widely in research on job design, especially on the motivational approach. More importantly, questionnaires are a very inexpensive, easy, and flexible way to measure work design characteristics. Moreover, they gather information from job experts, such as incumbents, supervisors, and engineers and other analysts.

Several questionnaires exist for measuring the motivational approach to job design (Hackman and Oldham, 1980; Sims et al., 1976), but only one questionnaire, the
multimethod job design questionnaire, measures characteristics for all four approaches to job design. This questionnaire (presented in Table 2) evaluates the quality of a job’s characteristics based on each of the four approaches. The team design measure (presented in Table 4) evaluates the quality of work design based on the team approach.

Questionnaires can be administered in a variety of ways. Employees can complete them individually at their convenience at their work station or some other designated area or they can complete them in a group setting. Group administration allows greater standardization of instructions and provides the opportunity to answer questions and clarify ambiguities. Managers and engineers can also complete the questionnaires either individually or in a group session. Engineers and analysts usually find that observation of the work site, examination of the equipment and procedures, and discussions with any incumbents or managers are important methods of gaining information on the work before completing the questionnaires.

Scoring for each job design approach or for each team characteristic on the questionnaires is usually accomplished by simply averaging the applicable items. Then scores from different incumbents, managers, or engineers describing the same job or team are combined by averaging. Multiple items and multiple respondents are used to improve the reliability and accuracy of the results. The implicit assumption is that slight differences among respondents are to be expected because of legitimate differences in viewpoint. However, absolute differences in scores should be examined on an item-by-item basis, and large discrepancies (e.g., more than one point) should be discussed to clarify possible differences in interpretation. It may be useful to discuss each item until a consensus rating is reached.

The higher the score on a particular job design scale or work team characteristic scale, the better the quality of the design in terms of that approach or characteristic. Likewise, the higher the score on a particular item, the better the design is on that dimension. How high a score is needed or necessary cannot be stated in isolation. Some jobs or teams are naturally higher or lower on the various approaches, and there may be limits to the potential of some jobs. The scores have most value in comparing different jobs, teams, or design approaches, rather than evaluating the absolute level of the quality of a job or team design. However, a simple rule of thumb is that if the score for an approach is smaller than 3, the job or team is poorly designed on that approach and it should be reconsidered. Even if the average score on an approach is greater than 3, examine any individual dimension scores that are at 2 or 1.

Uses of Questionnaires in Different Contexts:

1. Designing New Jobs or Teams. When jobs or teams do not yet exist, the questionnaire is used to evaluate proposed job or team descriptions, work stations, equipment, and so on. In this role, it often serves as a simple design checklist. Additional administrations of the questionnaire in later months or years can be used to assess the longer term effects of the job or team design.

2. Redesigning Existing Jobs or Teams or Switching from Job to Team Design. When jobs or teams already exist, there is a much greater wealth of information. Questionnaires can be completed by incumbents, managers, and engineers. Questionnaires can be used to measure design both before and after changes are made to compare the redesign with the previous design approach. A premeasure before the redesign can be used as a baseline measurement against which to compare a postmeasure conducted right after the redesign implementation. A follow-up measure can be used in later months or years to assess the long-term difference between the previous design approach and the new approach. If other sites or plants with the same types of jobs or teams are not immediately included in the redesign but are maintained with the older design approach, they can be used as a comparison or “control group” to enable analysts to draw even stronger conclusions about the effectiveness of the redesign. Such a control group allows one to control for the possibilities that changes in effectiveness were not due to the redesign but were in fact due to some other causes such as increases in workers’ knowledge and skills with the passage of time, changes in workers’ economic environment (i.e., job security, wages, etc.), or workers trying to give socially desirable responses to questionnaire items.

3. Diagnosing Problem Job or Team Designs. When problems occur, regardless of the apparent source of the problem, the job or team design questionnaires can be used as a diagnostic device to determine if any problems exist with the design of the jobs or teams.

5.2 Choosing Sources of Data

1. Incumbents. Incumbents are probably the best source of information for existing jobs or teams. Having input can enhance the likelihood that changes will be accepted, and involvement in such decisions can enhance feelings of participation, thus increasing motivational job design in itself (see item 22 of the motivational scale in Table 2). One should include a large number of incumbents for each job or team because there can be slight differences in perceptions of the same job or team due to individual differences (discussed in Section 4.1). Evidence suggests that one should include at least five incumbents for each job or team, but more are preferable (Campion, 1988; Campion and McClelland, 1991; Campion et al., 1993, 1995).

2. Managers or Supervisors. First-level managers or supervisors may be the next most knowledgeable persons about an existing work design. They may also provide information on jobs or teams under development. Some differences in perceptions of the same job or team will exist
among managers, so multiple managers should be used.

3. Engineers or Analysts. Engineers may be the only source of information if the jobs or teams are not yet developed. But also for existing jobs or teams, an outside perspective of an engineer, analyst, or consultant may provide a more objective viewpoint. Again, there can be differences among engineers, so several should evaluate each job or team.

It is desirable to get multiple inputs and perspectives from different sources in order to get the most reliable and accurate picture of the results of the job or team design.

### 5.3 Long-Term Effects and Potential Biases

It is important to recognize that some effects of job or team design may not be immediate, others may not be long lasting, and still others may not be obvious. Initially, when jobs or teams are designed, or right after they are redesigned, there may be a short-term period of positive attitudes (often called a “honeymoon effect”). As the legendary Hawthorne studies indicated, changes in jobs or increased attention paid to workers tends to create novel stimulation and positive attitudes (Mayo, 1933). Such transitory elevations in affect should not be mistaken for long-term improvements in satisfaction, as they may wear off over time. In fact, with time, employees may realize their work is now more complex and should be paid higher compensation (Campion and Berger, 1990).

Costs which are likely to lag in time also include stress and fatigue, which may take a while to build up if mental demands have been increased excessively. Boredom may take a while to set in if mental demands have been overly decreased. In terms of lagged benefits, productivity and quality are likely to improve with practice and learning on the new job or team. And some benefits, like reduced turnover, simply take time to estimate accurately.

Benefits which may potentially dissipate with time include satisfaction, especially if the elevated satisfaction is a function of novelty rather than basic changes to the motivating value of the work. Short-term increases in productivity due to heightened effort rather than better design may not last. Costs which may dissipate include training requirements and staffing difficulties. Once jobs are staffed and everyone is trained, these costs disappear until turnover occurs. So these costs will not go away completely, but they may be less after initial start-up. Dissipating heightened satisfaction but long-term increases in productivity were observed in a motivational job redesign study conducted by Griffin (1991). These are only examples to illustrate how dissipating and lagged effects might occur. A more detailed example of long-term effects is given in Section 5.8.

A potential bias which may confuse the proper evaluation of benefits and costs is spillover. Laboratory research has shown that the job satisfaction of employees can bias perceptions of the motivational value of their jobs (O’Reilly et al., 1980). Likewise, the level of morale in the organization can have a spillover effect onto employees’ perceptions of job or team design. If morale is particularly high, it may have an elevating effect on how employees or analysts view the jobs or teams; conversely, low morale may have a depressing effect on views. The term morale refers to the general level of job satisfaction across employees, and it may be a function of many factors, including management, working conditions, and wages. Another factor which has an especially strong effect on employee reactions to work design changes is employment security. Obviously, employee enthusiasm for work design changes will be negative if they view them as potentially decreasing their job security. Every effort should be made to eliminate these fears. The best method of addressing these effects is to be attentive to their potential existence and to conduct longitudinal evaluations of job and team design.

In addition to questionnaires, many other analytical tools are useful for work design. The disciplines that contributed the different approaches to work design have also contributed different techniques for analyzing tasks, jobs, and processes for design and redesign purposes. These techniques include job analysis methods created by specialists in industrial psychology, variance analysis methods created by specialists in sociotechnical design, time-and-motion analysis methods created by specialists in industrial engineering, and linkage analysis methods created by specialists in human factors. This section briefly describes a few of these techniques to illustrate the range of options. The reader is referred to the citations for detail on how to use the techniques.

### 5.4 Job Analysis

Job analysis can be broadly defined as a number of systematic techniques for collecting and making judgments about job information (Morgeson and Campion, 1997, 2000). Information derived from job analysis can be used to aid in recruitment and selection decisions, determine training and development needs, develop performance appraisal systems, and evaluate jobs for compensation as well as analyze tasks and jobs for job design. Job analysis may also focus on tasks, worker characteristics, worker functions, work fields, working conditions, tools and methods, products and services, and so on. Job analysis data can come from job incumbents, supervisors, and analysts who specialize in the analysis of jobs. Data may also be provided by higher management levels or subordinates in some cases.

Considerable literature has been published on the topic of job analysis (Ash et al., 1983; Dierdorff and Wilson, 2003; Gael, 1983; Harvey, 1991; Morgeson and Campion, 1997; Morgeson et al., 2004; Peterson et al., 2001; U.S. Department of Labor, 1972). Some of the more typical methods of analysis are briefly described below:

1. **Conferences and Interviews.** Conferences or interviews with job experts, such as incumbents and supervisors, are often the first step. During such meetings, information collected typically includes job duties and tasks, KSAs, and other worker characteristics.
2. **Questionnaires.** Questionnaires are used to collect information efficiently from a large number of people. Questionnaires require considerable prior knowledge of the job to form the basis of the items (e.g., primary tasks). Often this information is first collected through conferences and interviews, and then the questionnaire is constructed and used to collect judgments about the job (e.g., importance and time spent on each task). Some standardized questionnaires have been developed which can be applied to all jobs to collect basic information on tasks and requirements. Examples of standardized questionnaires are the position analysis questionnaire (McCormick et al., 1972) and the Occupational Information Network (O*NET; Peterson et al., 2001).

3. **Inventories.** Inventories are much like questionnaires, except they are simpler in format. They are usually simple checklists where the job expert checks whether a task is performed or an attribute is required.

4. **Critical Incidents.** This form of job analysis focuses only on aspects of worker behavior which are especially effective or ineffective.

5. **Work Observation and Activity Sampling.** Quite often job analysis includes the actual observation of work performed. More sophisticated technologies involve statistical sampling of work activities.

6. **Diaries.** Sometimes it is useful or necessary to collect data by having the employee keep a diary of activities on his or her job.

7. **Functional Job Analysis.** Task statements can be written in a standardized fashion. Functional job analysis suggests how to write task statements (e.g., start with a verb, be as simple and discrete as possible). It also involves rating jobs on the degree of data, people, and things requirements. This form of job analysis was developed by the U.S. Department of Labor and has been used to describe over 12,000 jobs as documented in the *Dictionary of Occupational Titles* (Fine and Wiley, 1971; U.S. Department of Labor, 1977).

Very limited research has been done to evaluate the practicality and quality of various job analysis methods for different purposes. But analysts seem to agree that combinations of methods are preferable to single methods (Levine et al., 1983; Morgeson and Campion, 1997).

Current approaches to job analysis do not give much attention to analyzing teams. For example, the *Dictionary of Occupational Titles* (U.S. Department of Labor, 1972) considers “people” requirements of jobs but does not address specific teamwork KSAs. Likewise, recent reviews of the literature mention some components of teamwork such as communication and coordination (e.g., Harvey, 1991) but give little attention to other teamwork KSAs. Thus, job analysis systems may need to be revised. The recent O*NET reflects a major new job analysis system designed to replace the *Dictionary of Titles* (Peterson et al., 2001). Although not explicitly addressing the issue of teamwork KSAs, it does contain a large number of worker attribute domains that may prove useful. Teamwork KSAs are more likely to emerge with conventional approaches to job analysis because of their unstructured nature (e.g., interviews), but structured approaches (e.g., questionnaires) will have to be modified to query about teamwork KSAs.

### 5.5 Other Approaches

Variance analysis is a tool used to identify areas of technological uncertainty in a production process (Davis and Wacker, 1982). It aids the organization in designing jobs to allow job holders to control the variability in their work. See Chapters 12 and 13 in this handbook for more information on task and workload analysis.

Industrial engineers have also created many techniques to help job designers visualize operations in order to improve efficiencies, which has led to the development of a considerable literature on the topic of time-and-motion analysis (e.g., Mundel, 1985; Niebel, 1988). Some of these techniques are **process charts** (graphically represent separate steps or events that occur during performance of a task or series of actions); **flow diagrams** (utilize drawings of an area or building in which an activity takes place and use lines, symbols, and notations to help designers visualize the physical layout of the work); **possibility guides** (tools for systematically listing all possible changes suggested for a particular activity or output, and examine the consequences of suggestions to aid in selecting the most feasible changes); and **network diagrams** (describe complex relationships, where a circle or square represents a “status,” a partial or complete service, or substantive output; heavy lines represent “critical paths,” which determine the minimum expected completion time for a project).

Linkage analysis is another technique used by human factors specialists to represent relationships (i.e., “links”) between components (i.e., people or things) in a work system (Sanders and McCormick, 1987). Designers of physical work arrangements use tools (i.e., link tables, adjacency layout diagrams, and spatial operational sequences) to represent relationships between components in order to better understand how to arrange components to minimize the distance between frequent or important links.

### 5.6 Example of an Evaluation of a Job Design

Studies conducted by Campion and McClelland (1991, 1993) are described as an illustration of an evaluation of a job redesign project. They illustrate the value of considering an interdisciplinary perspective. The setting was a large financial services company. The units under study processed the paperwork in support of other units that sold the company’s products. Jobs had been designed in a mechanistic manner such that individual employees prepared, sorted, coded, and computer input the paper flow.

The organization viewed the jobs as too mechanistically designed. Guided by the motivational approach, the project intended to enlarge jobs by combining existing...
JOBS AND TEAM DESIGN

In order to attain three objectives: (1) enhance motivation and satisfaction of employees, (2) increase incidence feelings of ownership of the work, thus increasing customer service, and (3) maintain productivity in spite of potential lost efficiencies from the motivational approach. The consequences of all approaches to job design were considered. It was anticipated that the project would increase motivational consequences, decrease mechanistic and perceptual/motor consequences, and have no effect on biological consequences (Table 1).

The evaluation consisted of collecting detailed data on job design and a broad spectrum of potential benefits and costs of enlarged jobs. The research strategy involved comparing several varieties of enlarged jobs with each other and with unenlarged jobs. Questionnaire data were collected and focused team meetings were conducted with incumbents, managers, and analysts. The study was repeated at five different geographic sites.

Results indicated enlarged jobs had the benefits of more employee satisfaction, less boredom, better quality, and better customer service, but they also had the costs of slightly higher training, skill, and compensation requirements. Another finding was that all potential costs of enlarging jobs were not observed, suggesting that redesign can lead to benefits without incurring every cost in a one-to-one fashion.

In a two-year follow-up evaluation study, it was found that the costs and benefits of job enlargement changed substantially over time, depending on the type of enlargement. Task enlargement, which was the focus of the original study, had mostly long-term costs (e.g., lower satisfaction, efficiency, and customer service and more mental overload and errors). Conversely, knowledge enlargement, which emerged as a form of job design since the original study, had mostly benefits (e.g., higher satisfaction and customer service and lower overload and errors).

There are several important implications of the latter study. First, it illustrates that the long-term effects of job design changes can be different than the short-term effects. Second, it shows the classic distinction between enlargement and enrichment (Herzberg, 1966) in that simply adding more tasks did not improve the job, but adding more knowledge opportunities did. Third, it illustrates how the job design process is iterative. In this setting, the more favorable knowledge enlargement was discovered only after gaining experience with task enlargement. Fourth, as in the previous study, it shows that it is possible in some situations to gain benefits of job design without incurring all the potential costs, thus minimizing the trade-offs between the motivational and mechanistic approaches to job design.

5.7 Example of an Evaluation of a Team Design

Studies conducted by the authors and their colleagues are described here as an illustration of an evaluation of a team design project (Campion et al., 1993, 1995). They illustrate the use of multiple sources of data and multiple types of team effectiveness outcomes. The setting was the same financial services company as in the example job design evaluation above. Questionnaires based on Table 4 were administered to 391 clerical employees in 80 teams and 70 team managers in the first study (Campion et al., 1993) and to 357 professional workers in 60 teams (e.g., systems analysts, claims specialists, underwriters) and 93 managers in the second study (Campion et al., 1996) to measure teams’ design characteristics. Thus, two sources of data were used, team members and team managers, to measure the team design characteristics.

In both studies, effectiveness outcomes included the organization’s employee satisfaction survey, which had been administered at a different time than the team design characteristics questionnaire, and managers’ judgments of teams’ effectiveness, measured at the same time as the team design characteristics. In the first study, several months of records of team productivity were also used to measure effectiveness. Additional effectiveness measures in the second study were employees’ judgments of their team’s effectiveness, measured at the same time as the team design characteristics, managers’ judgments of teams’ effectiveness, measured a second time three months after the team design characteristics, and the average of team members’ most recent performance ratings.

Results indicated that all of the team design characteristics had positive relationships with at least some of the outcomes. Relationships were strongest for process characteristics, followed by job design, context, interdependence, and composition characteristics (see Figure 1). Results also indicated that when teams were well designed according to the team design approach, they were higher on both employee satisfaction and team effectiveness ratings than less well designed teams.

Results were stronger when the team design characteristics data were from team members, rather than from the team managers. This illustrates the importance of collecting data from different sources to gain different perspectives on the results of a team design project. Collecting data from only a single source may lead one to draw different conclusions about a design project than if one obtains a broader picture of the team design results from multiple sources.

Results were also stronger when outcome measures came from employees (employee satisfaction, team member judgments of their teams), managers rating their own teams, or productivity records, than when they came from other managers or from performance appraisal ratings. This illustrates the use of different types of outcome measures to avoid drawing conclusions from overly limited data. This example also illustrates the use of separate data collection methods and times for collecting team design characteristics data versus team outcomes data. A single data collection method and time in which team design characteristics and outcomes are collected from the same source (e.g., team members only) on the same day can create an illusion of higher relationships between design characteristics and outcomes than really exist. Although it is more costly to use multiple sources, methods, and administration times, the ability to draw conclusions from the results is far stronger if one does.
